

BANKING MANAGEMENT SYSTEM

WEEK 2 – HASHMAP STORAGE

ABSTRACTION

The Banking Management System is a console-based Java application designed to perform basic banking operations such as account creation, money deposit, money withdrawal, and balance checking. The system is developed in a modular and object-oriented manner.

In Week 2, the application uses **HashMap<Integer, Account>** for storing account information. Here, the Account ID is used as the key and the Account object is used as the value.

This structure allows direct and efficient retrieval of account details using the **get()** method of HashMap, eliminating the need for manual searching using loops. It also helps in preventing duplicate Account IDs using the **containsKey()** method.

Encapsulation is applied to protect account data by keeping the attributes private and providing public methods for controlled access and modifications.

All data is stored in memory only. Since no file handling or database is used in this week, the data will be lost once the program terminates.
