

ABSTRACTION

Banking Management System (Week 1)

The Banking Management System is a console-based application developed using **Java**. The main objective of this system is to perform basic banking operations such as creating an account, depositing money, withdrawing money, and checking account balance. The system provides a simple menu-driven interface that allows users to interact and perform these operations easily.

In Week 1, the system uses an **ArrayList** to store account information in memory. Each account is represented as an object of the **Account** class, which contains private data members such as account ID, account holder name, and balance. Encapsulation is applied by keeping the data private and providing public methods to access and modify the data, ensuring data security and integrity.

The system uses manual for/while loops to search for accounts and validate data, including preventing duplicate account IDs. All data is temporary and will be lost when the program terminates, as no file handling or database is used in this week.

This abstraction focuses on the core functionality and simplicity of the system, forming the foundation for future enhancements such as advanced data structures, file storage, and data persistence.
